Working Papers

Raising Revenues: Evidence from Property Tax Assessments in India *(Job Market Paper)*

Abstract: How do property-owners respond to increases in property-tax liabilities? Particularly, do these responses differ across the initial-liability distribution, and how does accounting for this heterogeneity affect the revenue-maximizing tax rate? I construct a novel dataset of geolocated properties and digitised parcel-level maps from an Indian municipality to answer this question. I exploit variation in liabilities that arise from area-based guidance values that are fixed as of 2011, known as 'circle rates'. First, I find that a 1% increase in the circle rate reduces compliance by 0.45% but increases total revenues by 0.85%. This implies that revenues are maximized by scaling every circle rate by a common factor of 4.011. This preserves the existing relative circle rate schedule while increasing liabilities proportionally across properties, and is equivalent to increasing the statutory tax rate from 0.25% to approximately 1.00%. Second, I find statistically significant differences in compliance elasticities across the circle rate distribution, with larger responses at higher rates. Incorporating this reduces the revenue-maximizing scaling factor to 2.217, equivalent to increasing the statutory tax rate to 0.55%. Third, I find that updating liabilities to reflect revenue maximising schedules leads to large gains in revenue, but simply updating outdated circle rates to more recent values recovers a substantial share of these gains.

Bridging the Solar Divide: Demand Responses to Subsidies among Low-Income Households with Rui Zhong
Abstract: Governments increasingly rely on subsidies to encourage household adoption of clean technology, yet credible estimates of demand elasticities for low-income households, remain limited. In this paper, we study demand responses to solar subsidies in California, using an RDD and find a large price elasticity of -1.73. Low-income households are sensitive to the price they pay but may be served better by smaller panels that cost less.

Political Economy of State Borrowing and Financial Crowding Out with Viral Acharya, Nirupama Kulkarni, and Rahul Singh Chauhan
Abstract: Using regulatory primary auction data of state government securities, we find states with the same ruling party as the central government increase issuance by 28% at 43 bps lower yields in the year before elections. The crowding out mechanism operates through government-owned banks, who bid 23% higher amounts and at a 70 bps discount relative to other bidders. Consequently, firms with a 10% higher share of PSB borrowing see a 9.3% reduction in debt. Finally, we establish the underlying political economy channel wherein aligned states increase consumption expenditure, which increases the probability of the ruling party getting re-elected.
